NUTS NOTES.

Vol 9 No 2

Editor: Andrew Huxtable Summer 1971

EDITORIAL

Dare I mention it, but the first (and last) item we had from a female NUTS member appeared over 5 years ago! This issue includes a brilliant article by Carole Endersby which, it is hoped, will be followed by another on the use of stimulants (amphetamines, etc).

Members who require photocopies of back issues of NUTS Notes should send a list of their requirements to Dave Terry, 5 Grange Close, Heston, HOUNSLOW, Middx; enclosing 3p in stamps for every five issues.

I have copies of the following publications: enclose 5p for each please.

Austrian Yearbook 1970 1 Norwegian Yearbook 197110 European Top 100 lists 1970 3 CSSR All Time Women's lists 4 World Record Evolution 4

The next issue of NUTS Notes will be published in October; please send your contribution to reach me by the end of September.

MISCELLANY

ß As many of you will have seen (in the "Sunday Times") and heard (on the BBC Radio 4 programme "Now Read On") Peter Lovesey has achieved further fame: his first effort at crime fiction - the award-winning "Wobble to Death" - has had the film rights bought by Carl Foreman for Columbia and filming will probably start next year. Foreman, born Chicago 23 July 1914, directed "The Victors" and was scriptwriter for, <u>inter alia</u>, "High Noon", "The Bridge on the River Kwai" and "The Guns of Navarone". "The book",writes Peter, "has been an extraordinarily lucky one for me. Besides winning the £1,000 Macmillan/Panther Award and appearing in hardback and paperback here, it has been published in America and translations are being made for editions in Finland, France, Germany and Japan". His latest work, "The Detective wore Silk Drawers" (Macmillan, £1.40) is highly recommended. The paperback rights have already been sold, as also have the US and French publishing rights!

§ Margaret Gould asks me to mention that if you phone her new home you should wait a couple of hours or so while she negotiates two flights of stairs.

§ Congratulations to Martin and Barbara James on the birth of Matthew Edward (23 June, 3.54 kg/71b 13oz).

§ New ventures: Tom Pollak reporting on athletics for BBC Radio London and Dave Cocksedge pole vaulting. Under the guidance of a certain Brian Hooper the latter has reached 2.74 in training: his competitive debut is eagerly awaited.

WHAT'S IN A (COMMON) NAME? by Richard Szreter

According to the Penguin Dictionary of Surnames (by B Cottle), Smith is "easily the commonest surname in England and Wales", with Jones second ("notoriously the commonest surname in Wales alone", though), Williams third, and Taylor just "out of the medals" in fourth spot.(well, the last two may have slipped down since the count of 1853 quoted). But it's the Taylors that turn up trumps in the handsome new 1971 annual; among men anyway - women cheat by changing names, so I left them out of this exercise. Led by the indefatigable Dick, the Taylor clan have mustered a full score-but-one entries in the index, the Williamses notched up 14, the name of Jones appeared a dozen times, and there were barely 11 Smiths (no, I won't let them have the odd Smyth). An exact reversal of "form", in fact!

Not being satisfied with the size of the sample, I decided to look at three seasons at what seemed to be reasonable intervals of 3 years. The count in the 1964, 1967 and 1970 annuals revealed thereupon the following figures: Smith 33 times, Jones 43, Williams 36, Taylor 38. It's no easy

There has been a good deal of controversy recently concerning the advisability of banning the use of steroids in athletic training. This article aims to give a general picture of our present state of knowledge of the substances involved, so that one may, perhaps, be able to make up one's own mind more easily.

It was realised in the time of primitive man that castration in boyhood prevented the occurrence of puberty. In 1771 John Hunter induced male characteristics in the hen by transplanting testes from the cock (1) but the discovery that the testis is a secretory gland is usually credited to Berthold who in 1849 showed that the transplant of testes into castrated roosters prevented the typical signs of castration. Many attempts were made to isolate the active testicular substance, largely because of the popular belief that failure of testicular function was the cause of the symptoms of old age.

Before the chemistry of the male sex hormones could be elucidated it was necessary to develop methods of measuring the amounts of hormone present in biological samples. A widely used procedure was the determination of hormonal activity in terms of the growth response of the capon's comb; in fact, the method was used as a guide in the chemical isolation of active substances from urine. Butendant (2) was the first to succeed in this field and in 1932 he proposed a structural formula for the hormone which he had isolated that was later confirmed by synthesis in the laboratcry (3). It became apparent that extracts of the testes differed in chemical and physiological characteristics from the substance that had been isolated from urine; for example, testicular extracts that were of equal potency to the urinary extract in promoting growth of the capon's comb had a much greater effect on the seminal vesicles of castrated rats. Active testicular extracts were prepared as early as 1927 by Loewe (4) and the substance was isolated in crystalline form by Laquem (5) in 1935. The chemical structure was soon elucidated and the hormone was synthesised by Ruzicka and Wettstein in 1935 (6): this hormone was called testosterone.

A great many other substances with similar activity then became known; some were isolated from ovaries and adrenal glands and others were prepared synthetically. All these substances are classified chemically as steroids. Their molecules are mostly composed of the same groups of atoms but each is characterised by certain special groups of atoms substituted at particular places in the molecule. These substances, related in structure and function to testosterone, are collectively known as androgens and tend to produce the same range of physiological effects (androgenic actions) but differ in the extent to which they produce one action rather than another.

Androgenic actions

The androgens are responsible for the changes that transform a boy into a man at puberty, and for the maintenance of these secondary sexual characteristics. They also influence testicular function by two means: indirectly through their influence on pituitary hormone output and directly on the seminiferous tubules of the testis, stimulating production of sprmatozoa. The pituitary gland lies at the base of the brain and secretes hormones which act on the testis: one stimulates the cells (seminiferous tubules) in which spermatozoa develop and another acts on a different population of testicular cells (Leydig cells) causing testosterone to be released. The testosterone circulating in the blood then inhibits the pituitary hormonal output so that the appropriate balance of hormones is attained - an example of a negative feedback mechanism. This is, however, a somewhat simplified representation of the system.

Anabolic actions

Androgens were found to produce a retention of nitrogen in the body when urinary extracts were injected into castrated dogs. Soon afterwards, in 1938, Papanicalaou and Falk (8) showed the skeletal muscles of male guinea pigs to be much larger than those of the female, and the difference abolished by removal of the testes. Injection of testosterone into the female or the castrated male caused pronounced muscular development, showing that the large muscles of the male are dependent upon androgens. The nitrogen retained by androgens (along with other elements) is necessary for protoplasm to be formed, and so for muscle tissue to be built up, and this is known as an anabolic effect.

All the steroids synthesised so far produce both androgenic and anabolic effects, although one type type of action is often dominant. Since the anabolic actions can be therapeutically useful, the aim is to produce steroids with potent anabolic effects and negligible androgenic actions. Side effects

Steroids with anabolic actions are used clinically in patients with growth disorders and to promote tissue growth after illness; they are also used in women suffering from osteopoiosis (excessive porousness of the bones due to a decrease in oestrogen production after the menopause), and in the treatment of cancer of the breast. However, apart from their therapeutic effects, the steroids also produce unwanted side-effects. In women, all androgens are likely to produce masculinisation, which is initially manifested as acne, the growth of facial hair and hoarsening or deepening of the voice. These symptoms will slowly subside if treatment is discontinued but otherwise there may also develop the male pattern of baldness, excessclitoris - a largely irreversible phenomenon.

Retention of water in association with sodium chloride usually occurs after administration of an androgen, and accounts for some of the weight gain in short-term treatment.

Many of the steroids cause a type of liver damage known as cholestatic hepatitis, jaundice being the principal clinical feature. This is due to an accumulation of bile in the smaller ducts of the liver and to minor changes in the cells. As androgens are broken down in the liver, this cholestasis will result in an accumulation in the body of the steroid and its breakdown products. For this reason treatment often takes the form of short courses of steroid interrupted by intervals without the drug. Steroids can also produce undesirable effects by changing the amounts of enzymes in the blood and of the proteins necessary to transport the thyroid hormone around the body. An increase in athletic performance is believed to occur as a result of treatment with a steroid with anabolic actions, accompanied by a high protein diet (to supply the constituents for new muscle tissue) and training. However, there is some dispute over this fact designed.

Fowler (9) observed no effect of the anabolic steroids on physical performance of young, healthy men, even in a group taking extra exercise. But the exercise may have been less strenuous than athletic training, and so does not present a strictly comparable situation.

The picture is obviously not yet clear but it is the balance of the increase in athletic performance weighed against the possible side effects which must determine one's decision on whether or not steroid treatment should be allowed in sport. (This is from the purely physiological viewpoint; moral issues are obviously equally important.)

A further difficulty is that, even if anabolic steroids are banned, it is practically impossible to enforce the rule. Since the effects on muscular development are prolonged, the athlete can stop treatment weeks before a competition so that no drug will be detected. Furthermore, only a limited number of the steroids can at present be measured, and this involves an expensive and time-consuming technique.

Age records are often published for Junior age-groups, but this may⁴ be the first time such records have been published for U.K. atkletes for other ages. I would thus welcome amendments to the ensuing lists which I hope to continue in future issues of NUTS Notes.
